

Programming lesson #1a "C in 4 pages"

1) This is a 'C' program:

```
#include <stdio.h> ← header file
```

```
#define PI 3.14159 ← #define
```

```
int main(void)
```

```
{
```

```
    int x = 0;
```

```
    printf("%d\n", x);
```

```
    printf("%f\n", PI);
```

```
}
```

print function

How to format

what to print

variable

function

2) a 'C' program is just text in a particular style, set of rules

3) need to translate it to "machine code" using a compiler (gcc) before it can be run ("executed") on machine.:

```
gcc test.c -o test
```

4) To run this program:

```
./test
```

4a) modify test.c to print out your name, age.

Programming Lesson #16

'C' code continued

5) Here's another 'C' program:

```
#include <stdio.h>
```

```
#define PI 3.14159
```

```
int main(void)  
{
```

```
    int x = 15;
```

← semi-colon at
end of statement

```
    if (x > 10) {
```

```
        printf("x is big\n");
```

← NO semi-colon
at end of flow
control command

```
    }
```

```
    else
```

```
    {
```

```
        printf("x is puny\n");
```

```
    }
```

```
}
```

5a) add "if()" test for case where $x > 100$
and print something different out.

Programming Lesson #1c 'C' code continued

6) Another 'C' program:

```
#include <stdio.h>
```

```
#define PI 3.14159
```

```
int main (void)
```

```
{
```

```
    int i;
```

```
    for (i = 0 ; i < 1000 ; i++)
```

```
    {
```

```
        printf("%d\n", i);
```

```
    }
```

```
}
```

"for" loop

Ⓐ initializer

Ⓑ test

Ⓒ body

Ⓓ increment

this executes Ⓐ once and then Ⓑ, Ⓒ, Ⓓ over and over, in that order.

6a) change "for" loop to count to 1 million.

6b) change printf command to also print i squared.

Programming Lesson #1d 'C' code continued

7) last 'C' program (for now :-)

```
#include <stdio.h>

#define PI 3.14159

float negate (float value)
{
    return (-1.0 * value);
}

int main (void)
{
    float x = PI;
    float y;
    y = negate(x);
    printf ("%f\n", y);
}
```

Annotations:

- input**: points to the value `3.14159` in the `#define` statement.
- function**: points to the `negate` function definition.
- execution starts at main()**: points to the `main` function.
- pass input**: points to the argument `x` in the function call `negate(x)`.
- catches output**: points to the `printf` statement.

7a) add new function: `float square (float value);` that returns value squared.

7b) add `printf` to display "y" and "y" squared.
